

Genetic-environment interaction (GxE) in fish

Quantitative traits are usually controlled by several genes as well as by environment influences. Environments could include stocking density, feeding, water quality management, ...etc

Hence: the phenotype of an individual $(P) = G + E + G-E$

Whereas G= genetic make-up; E= environment & G-E= genetic-environment interaction

G-E exists when various genotypes perform differently in different environments

If compared genotypes maintained their rank in different environments \rightarrow **no G x E**

GXE (Example)

Genotype	Environment A	Environment B	
Strain A	80	60	No interaction
Strain B	60	40	
Strain A	80	60	Mild interaction
Strain B	60	60	
Strain A	80	50	Strong interaction
Strain B	60	70	

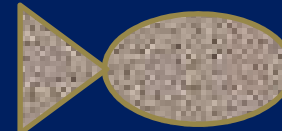

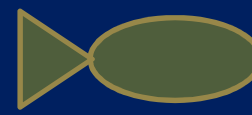

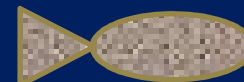

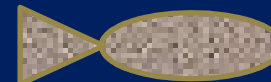

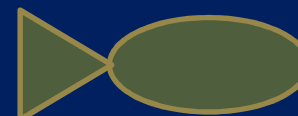

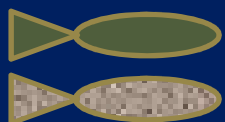

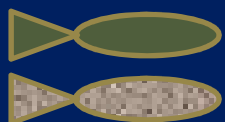

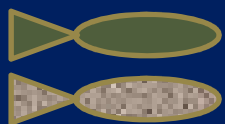

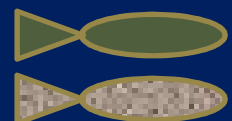

Genetic-Environment Interaction (GXE) in fish

Illustrated example:

Environment A: earthen ponds whereas the nutrition relies more on organic manure & supplemented by artificial feed

Environment B: earthen ponds with aeration and higher stocking density whereas complete artificial feed is the only source of nutrition

The data should be statistically analyzed and result of well-designed experiment starting with fish of the same size/age
