Fish Hatchery Management

Abdel Rahman El Gamal, PhD
Contents of this lecture

• Aquatic organisms (fact sheet)
• Modes of fish reproduction
• Naturally collected fry/broodstock
• Sexual maturation and broodstock management
• Fish hatcheries and hatchery technologies
• Nursing
• Conclusion
Aquatic organisms (fish) 
Introductory fact Sheet

• Cold Blooded Animals with the exception of a known species (Great white shark)
• Highly fecund animals compared to other animal groups even for low-fecund fish species
• Highly diversified group (finfish, crustaceans, molluscs, …)
• Living environments determine living fish species and their mode of reproducing (cold water, warm water, freshwater, marine water)
• Vary significantly in regard to the mode of their reproduction
### Fish Fecundity

**Notes:**

- Fecundity of fish species with large eggs (e.g. salmonids) is lower than fishes with small eggs.
- Generally, mouth brooders like Nile tilapia have low fecundities compared to substrate spawners such as *Tilapia zillii*.
- Live bearers such as mosquito fish give birth to small number of embryos.
Modes of fish reproduction

Egg layers - examples

- Substrate spawners

Egg retainers

- Ovoviviparous
  
  Each embryo develops in its own egg in female’s body until hatch. Embryos depend on their yolks

- Oviparous
  
  Majority of fish

- Live bearers (female or male)
  
  When male seahorse gives birth
  
  Mother retains the eggs and nourishes the embryos till they are born

- Mouth brooders
Commitment to death

American and European eels (genus *Anguilla*): Mature eels migrate from their freshwater rivers to the spawning grounds of their birth (Sargasso Sea); females lay eggs that are fertilized by males, then both males and females die.

Cuttlefish: Laid eggs are tended by the female until eggs hatch, and then both patents die.

Common Sydney octopus: Eggs laid are incubated by females for 25-45 days until eggs hatch, then female dies; during the incubation period females do not feed.

Credit: Dr. Sagiv Kolkovski
Parental care

- Spawning nest (tilapia)
- Fanning egg mass (channel catfish male)
- Mouth incubation (Nile tilapia)
- Taking fry in (Haplochromine cichlids)
- Hornet tilapia: deposit eggs in a hole dug by parents who attend their eggs until hatch
Collection of broodstock/fry from nature is done in case of:

- Naturally available/abundant (milkfish – mullet)
- No hatcheries/limited facilities
- Reproductive cycle is not closed (eels)
- Economic reasons (cheaper)
Disturbing mother nature

Human activities (over fishing)
Pollution (mass/selective effects)
Political conflicts (sturgeon & shared stocks)
Construction of dams (block migration)

Therefore

For the sake of sustainable development of aquaculture, the establishment of hatcheries become necessary
Old hatchery practices
Setting the stage (Common carp) – Dubisch pond

The Dubisch Pond has a raised center area that could be covered by water.

This area is covered with a spawning medium such as trimmed grass.

Selected pairs of broodstock once stocked, they spawn on the raised section – eggs stick to the grass.

Immediately after spawning, water is drained down; breeders move to the deep water where they are scooped.

The pond is filled again. As eggs hatch and grow to adequate size, they are collected for further nursing.

Dubisch ponds are typically 120 to 300 m² in surface and have an average depth of 30 – 60 cm

The relative shallowness and small area of the pond allow the water to warm quickly after filling

The shallow depth encourages the emergent grass which act as a substrate
Source of broodstock
From the wild

Recommended:

For First time ever

For stock enhancement programs (release) (Fish for natural systems are not the same fish for aquaculture)

Fish does not mature in captivity (until now)

Limitation in hatchery facilities (cannot handle the whole operation)

Economic reasons

BUT

Less reliable – could be affected by environmental factors
Abundance still have limits and could be affected by overfishing or higher demand
we have to accept what we get – no opportunity to perform breeding programs
Source of broodstock

From other hatcheries/fish farms

- More reliable
- More domesticated (for aquaculture)
- Possible application of breeding programs
- Possible conditioning for extended spawning seasons
- Better understanding of broodstock history (depending on the availability/quality of bookkeeping systems)
Over-feeding with carbohydrate rich or fatty diet should be avoided

The visceral fat in Indian carps and grass carp affected ovary development and impaired their response to artificial reproduction practices.

Placing fish in weedy habitats helped them to shed visceral fat allowing fish to spawn.

Mixing artificial feed of marine broodstock with squids/snail is believed needed for successful spawning.

For Asian seabass (Vietnam)
Photo credit: Ahmed Shaheen - Egypt
Broodstock – ponds/tanks

**Ponds**

Having sufficient number of broodstock ponds will help avoid too many fishing and so reduce stress and possible decline in the potency of fish.

Good match between outdoor ponds and indoor facility should be maintained.

A recovery pond for spent females **is a must**.

Depending on hatchery plan, a pond for common carp **may be considered** (donor to pituitary gland).

**Why common carp?**

- Mature earlier than many fish species
- Less costly to produce, maintain & sacrifice

**Tanks**

- Neither tank material nor paint should carry any harm to broodfish (e.g. toxic paint)
- Water flow should be adequate to fish biomass (**not excessive**)?
- Proper design allows self-cleaning
- Tanks are either covered or enough free board should be secured
- Air supply from oil-free air pumps
Hatchery Management – Water

### Quantity

For freshwater hatchery
Ponds of 5-ha require 40-50 l/second of water

For marine hatchery
Pumping capacity/h 50% of water volume

### Quality

Hatchery water should be:
- Low in turbidity
- High in DO
- Low in CO₂
- Extremely low in hydrogen sulfide (if any)
- Not super-saturation with nitrogen or other gases

Salinity (level & range): close to optimum

Temperature: close to optimum with minimum fluctuation

Heavy metals: case by case
Water Quality

We need to consider:
What could be accepted in a farm may not be tolerated in a hatchery
Copper and Zinc are damaging elements (no copper pipes, no zinc containers)
Hatchery management
Started complex (Cases)

1980 – Abbassa (common carp)

1982 – Sète/France (seabass, seabream)
Hatchery management
Turned easier- more towards natural systems

Open spawning system
Marine hatchery - Cyprus

Egg collection system
Marine hatchery - Kuwait

Hapa system
Tilapia hatchery - Egypt
Broodstock
Gonadal Development

- Gonads develop to a certain stage and remain dormant
- Further development will be triggered as suitable conditions exist producing ready to spawn
- Triggering factors include favored light & temperature, salinity, flood conditions, presence aquatic plants, presence of opposite sex
- Dormant stage continues if environmental changes are not too strong
- If environmental conditions get worse, the absorption of eggs takes place
Broodstock sorting

Sorting (based on gonad development)

Females:
- Ripest (ready to spawn)
- Promising
- Not different from males (discard)

Males:
- Ready
- Unready (discard)
Sexing and stage of maturation can be quite easy like below or may require additional work (e.g. Catheterization)/ Laparoscopy (sturgeon)

- Roughness of the dorsal surface of pectoral fins (male of grass carp)
- Tilapia
- African catfish
- Stage IV
Fish spawning could be classified as:

**Natural**: Tilapia, common carp, African catfish

**Some artificial**: Tilapia, some marine species, shrimp, others

**Artificial**: Chinese carps, common carp, some marine species, African catfish, others

The relatively low fecundity of tilapia does not allow its artificial spawning on commercial scale.
Natural Spawning

**Our responsibility is to:**
- Choose the ready broodstock
- Furnish the required facilities & environments
- Watch for the spawning

**Fish responsibility is to:**
- Get the work done
Artificial Spawning

Even the spawning is artificial, biological parameters still control

A broodstock must be ready in order to respond to the hormonal induction
Pituitary gland

- First use was in 1934 in Brazil
- Should be taken from sexually mature male or female
- Will be more effective when taken just prior to the spawning season
- One kg of common carp has a pituitary weighs 3 mg dry weight (pituitary is usually used by count and not by weight)
Artificial Spawning
(related to hormonal/other substances injection/)

- Hormones used for induced spawning **do not -by itself- produce** gametes (eggs or sperm)
- Hormones only trigger the release of fully developed gametes
- Fish must not only be sexually mature but should also be in the advanced stage of sexual development before induced spawning will be successful
- Sources of hormones could be the pituitary gland or other hormones (e.g. Human chorionic gonadotropin-HCG, Luteinizing Hormone Releasing Hormone - LHRH)
- HCG is a reliable marker of pregnancy in human
- Other substances rather than hormones may be used
Hormonal Administration

**IF:**
Fish are selected properly and Hormones are administered at the right time with the proper dose

Ovulation is expected

The overall protocols of hormonal induction vary from a species to another even for the same species

For batch spawners (e.g. gilthead seabream), slow release implants are used to release the hormone over the extended period of spawning

Full Spawners
Batch Spawners
Specific hormonal induction & eyestalk ablation in marine shrimp

Commercially adopted in the early 1970s

Eye stalk ablation removes x organ along with its contents of "Gonad Inhibiting Hormones"

Ablated shrimp has to be when hard-shelled, or in pre-molt stage

Final ovarian development/spawning within 3-10 days

Hopefully one eye stalk only

Ripening period (time between final hormonal dose and ovulation/stripping)
Ovulation

- Time of ovulation need to be watched
- Indicator fish may tell
- If eggs were not stripped at the appropriate time they turn overripe
- Over-ripe eggs do not fertilize
- Time between final injection and ovulation is ripening time (hour-grade)
Ovulation & stripping

Fertilization

Good quality milt = High rate of fertilization

One male or more?

Genetic considerations

Preserving milt

After the completion of fertilization, (dry or wet method), fertilized eggs (embryos) should be incubated till hatching

Done through:
- Direct use of live males
- Use of sacrificed male testes (African catfish)
- Preserved milt
Incubation — duration & facilities

Affected by:
- Species
- Type of eggs
- Environmental conditions

Key environmental factors are temperature and light

In general, incubation period could be as short as hours, few days for some species or as long as several months for other species.

*Note: the optimum thermal range for reproduction falls within survival range*
Types of fish eggs in relation to: incubation or treatment

- Mass (Channel catfish)
- Large Eggs (salmon)
- Loose Eggs (tilapia)
- Sticky eggs (carps)

Eggs of common Sydney octopus (2-mm eggs attached to 10-12 cm long string)

Spawning Operations
Catheterization (egg sampling)

Catheter should be of adequate size to match fish size and the urogenital pore

Careful manipulation and minimum force is needed to avoid the damage of sphincter muscles

If sphincter muscles got torn, eggs at the posterior end of the ovary will water-hardened, and the plug is formed

Improper catheterization may result in hemorrhage and clotting & blocking of egg flow during ovulation
Stripping (female size, handling)

A female with a size as such should be anesthetized
Watch for the effect of anesthesia on the sperm
Blood or broken eggs resulting from improper handling will reduce the rate of fertilization.

Protein from blood or broken eggs will coagulate and plug the micropyle reducing the rate of fertilization.

Placing eggs in 0.6% salt solution (fertilization solution) makes the protein to go back into solution.
Extending Solution (Ringer)

In 100 ml of water:

- Sodium chloride: 592 mg
- Potassium chloride: 172 mg
- Calcium chloride: 079 mg
- Magnesium sulfate: 031 mg

+ 100,000 units of penicillin
+ 100 mg of streptomycin

The practice allows better management of egg fertilization.
The sperm/solution could be stored for few days in refrigerator.
Sperm quality could be microscopically checked before use.

Sperm/Ringer need to be exposed to room temperature before use – otherwise they may develop thermal shock.

Photo credit: Roman Aszkiełowicz (Poland)
Deformity/Gas bubble disease

Due to temperature fluctuation

Check for Water Quality
Use de-aerating devices (can be simple)

Pop Eyes
Artificial (forced) hatching: this is done by drastically reducing water flow for few minutes), a normal flow of water must be restored immediately.

The delay can lead to suffocation and loss of the hatched embryos.
Synchronize hatching
Use of Independent temperature controlled incubators

Each single incubator in thermally controlled
This unique incubator’s establishment enables synchronizing the hatching of rainbow trout embryos

Hatching occurs at the same time for groups of different ages

Photo credit: Troutlodge Inc.
Embryonic Developments
Never mix different ages during incubation

A colored tub for each stage
Credit: Muhammad Iqbal (Pakistan)
Good or Bad Eggs

If eggs are heavily infected with fungus and other batches could be obtained:

Discard the whole bad batches
Incubation/temperature

It is much safer to incubate at highest safe temperature
(refer to an earlier table)
Hatchery Products (good or bad)
Replacing hatchery broodstock

Facts:
Young broodstock produce more eggs/g (relative fecundity), with shorter spawning intervals & much easier to handle. Replacing old broodstock by younger ones is often recommended.

No Fixed Rule

Replacing oldest age group  OR  Annually change 33%  OR  All-in & all-out

Compensating the missing sex & correcting the skewed sex ratio (in changing sex species – e.g. gilthead seabream: males change into females)
Early nursing (environment – feeding)

Water temperature is the most important single factor. Temperature range is acceptable; severe fluctuation should be avoided. (some species cannot tolerate temperature fluctuation that exceeds 0.5°C/day (seabass, seabream))

Light regime is critical for some species.

No matter where a larvae stays or moves, its food should be there.

The onset of the first larval feeding is a crucial step in the young fish life as starvation is a major cause of larval mortality.
While management may apply to almost all species

**Because in biology nothing is exact**

Modification in hatchery operations may take place according to species

Some steps may be omitted, others may be added

In brief, study your species
When facility begins by incubation

Incubating the fertilized eggs of sturgeon hybrids in Uruguay
Credit: Alejandro Perretta

Incubating the fertilized eggs of all-female of rainbow trout
Credit: Troutlodge (USA)

A carrying-egg female of freshwater prawn
Management and scale of production

Usually apply to large hatcheries

Abbassa – Egypt
(15 million tilapia fry/year)

Aswan - Egypt
Management and scale of production should also apply to small-scale hatcheries (e.g. tilapia hatcheries)

Chipata - Zambia

Fayoum - Egypt
Extending the spawning season

- Manipulating of photoperiod and/or temperature are the key factors for extending the spawning season outside the natural season
- The technique is in practice for several fish species
- This allows the production of seeds according to marketing and/or farming needs

Green houses help to produce tilapia at the time suitable to farms (Egypt)

Chilling, heating and light manipulation are used in marine hatcheries (Italy)
Enhancing Hatchery Efficiency
Multi-species – multi-sizes – enhanced quality

Sea Bass
Sea bream
Soles
Shrimp

Multi-species concept applies to either freshwater or marine hatchers

Production of different sizes of the same species is possible if technically and/or economically feasible

Screening for disease causing agents

Vaccination
Conclusion

• A hatchery is not a farm in regard to management and specific targets
• Quality of hatchery products is often seen on the farms
• For production economics, proper hatchery facility never means over-equipped hatchery
• Hatcheries are the place of genetics applications
• In the planning process, target species, possible additional species and hatchery products (e.g. fry, fingerlings, fertilized eggs), should be clearly defined
• Any change/improvement in the hatchery applications has to be economically justified or **Drop the idea**
• Competition, economics, quality control are issues to be considered in order for the hatchery activity to remain sustainable
